## ABSTRACT

# What this project is about

The Local Service Booking App is a web-based platform designed to connect customers with nearby service providers such as electricians, plumbers, carpenters, cleaners, and technicians.

Built on a robust relational database, the system stores and manages information about users, service providers, bookings, service categories, and payments in a structured and secure manner.

It eliminates the inefficiencies of manual, word-of-mouth service discovery by offering real-time availability, transparent pricing, booking history, and provider ratings — all backed by a well-normalized database schema.

Unified Platform

24/7

Booking Access

3NF

Normalized Schema

# Why the current approach falls short

## No Central Discovery

Customers rely on word-of-mouth or scattered ads to find local service providers, with no single trusted place to search.

## Manual Scheduling

Bookings happen over phone calls, often causing double-bookings, missed appointments, and no record of history.

## No Price Transparency

Service rates vary informally with no upfront visibility, making cost comparison difficult for customers.

## No Accountability

There is no structured way to rate providers or track service quality, leading to inconsistent trust.

# From manual coordination to a managed database system

| Aspect             | Existing System                        | Proposed System                                         |
|--------------------|----------------------------------------|---------------------------------------------------------|
| Service discovery  | Word-of-mouth, local ads, no directory | Searchable provider directory by category & location    |
| Booking process    | Phone calls, manual diary entries      | Real-time online booking with database validation       |
| Data storage       | No structured records; paper/registers | Centralized relational database (normalized tables)     |
| Availability check | Not tracked; frequent conflicts        | Live availability tracked via booking table constraints |
| Feedback & ratings | Informal, unrecorded                   | Structured rating & review table linked to bookings     |
| Scalability        | Difficult to expand or manage          | Easily scalable with structured schema & queries        |

# Proposed 3-tier architecture

# Tools and technologies we learnt and used

## Frontend

HTML5, CSS3, JavaScript / React

## Database

MySQL — schema design & normalization

## Modeling

ER Diagrams, DFDs (drawn using MySQL Workbench)

## Dev Tools

VS Code, Git & GitHub for version control
